People who carry out safe shopping online via a portable device are usually less willing to commit to a purchase than desktop users because of the way sites are displayed, according to a new study by researchers at the University of East Anglia.

Retail Times reports that this difference in habits has been identified in the wake of the festive period where sales and offers are rife, meaning that bargain hunters are willing to take a little more time to check they are getting the best possible deal.

Less than a third of people who began the process of placing an order from a portable gadget ultimately went through with the transaction, analysts discovered. This is in spite of the fact that almost half of all e-commerce site visits are now carried out using a mobile or tablet.

Study spokesperson, Dr Nikolaos Korfiatis, said that while m-commerce was portrayed as making safe shopping online simpler, the reality is that consumers are actually more cautious about making purchases due to a phenomenon known as 'emotional ambivalence'. In effect, this means that a combination of factors, including questions over the security of buying from a smartphone, make cart abandonment much more common.
